(54) Title: **NOZZLE ARRAY**

(57) Abstract: The invention relates to a nozzle array for use in the coating of a mobile web-like material, comprising a plurality of high-pressure nozzles (2.1, 2.2) in the transverse direction of the web. The nozzles (2.1, 2.2) have been classified by a variable acting on the flow so that the deviation of the variable within the array is smaller than a pre-set value. The yield of each nozzle being the same with optimal precision, an optimally even coating is achieved on the web.

WO 03/060233 A1

NOZZLE ARRAY

Technological background

- 5 The invention relates to the coating of a mobile web-like material with high-pressure spraying techniques and is directed to the nozzle array used in such coating. The invention is especially applicable to paper coating.

10 In paper coating, a liquid coating mixture intended especially to improve printability is applied to the paper surface. Presses, blade applicators and film transfer devices are conventionally used for this purpose. When an increase in the drive rate is called for or papers with continually decreasing thickness are coated, these techniques are difficult to implement reliably in the practice.

- 15 Spray coating has appeared as one of the most recent coating techniques. It has the particular advantage of not requiring any mechanical coating means in contact with the web, such as an abrasive blade or a rotating rod. The spray technique called high-pressure spray technique has proved particularly promising; it comprises driving merely a coating mixture without any gaseous medium under high pressure
- 20 through a nozzle with a small hole, so that the mixture is atomised into small droplets. The pressure may be e.g. 1...200 MPa and the nozzle opening area e.g. 0.02...0.5 mm². A typical maximum droplet size is about 100 µm. Such an apparatus comprises a nozzle array with one or more nozzle rows consisting of several nozzles in the transverse direction of the web. The nozzles are disposed so as to provide a
- 25 coating jet on the web that covers the web as evenly as possible. Then the jets generated by adjacent nozzles in a nozzle row suitably overlap at their edges. The coating mixture is distributed under the same pressure from one single feed pipe to each nozzle. This allows the flow of only the nozzles fed together to be adjusted by varying the pressure, the concentration or the viscosity. The jet shape provided by the
- 30 nozzles depends on the shape of the nozzle opening. The general aim is to provide a jet having a larger width in the transverse direction of the web than in its longitudinal direction. The nozzle opening is then accordingly oval.

- 35 Paper coating by spraying is described e.g. in the publications FI B 108061 (corresponding to WO 9717036) and Nissinen V, OptiSpray, the New Low Impact Paper

Coating Technology, OptiSpray Coating and Sizing Conference, Finland, 15 March 2001.

General description of the invention

5

A nozzle array as defined in claim 1 has now been invented for use in coating of a web-like material. The other claims describe some preferred embodiments of the invention.

- 10 It has now been found that deviation in the dimensions of the nozzle openings has a substantial impact both on the flow passing through the nozzle (yield) and on the jet shape. This results in a corresponding deviation of the coating formed on the web. Accordingly, it has been found that classifying the nozzles in advance on the basis of a variable correlating with the yield deviation can diminish the yield deviation of the nozzle array. The nozzles are classified so as to keep the deviation of the variable from the mean within the array under the permissible quality requirement. The requirement may be e.g. under $\pm 5\%$, such as under $\pm 2\%$.

- 20 The nozzle variable to be measured may be especially the nozzle opening area. The area can be determined especially by optical methods. The determination may e.g. comprise leading a light beam, such as a laser beam, to the opening, and measuring the portion of the beam retained by the opening. The area can also be directly obtained e.g. as pixels on the image surface of a CCD camera. Instead of the area, the width and the length of the opening can be determined, using their product as a variable. These can also be optically determined using a microscope, for instance. Optical measuring methods are also easy to automate.

- 30 With the nozzles classified as described above, the nozzle array yields a coating distribution on the web that is as even as possible and also remains as even as possible as the nozzles wear. The coating can be achieved with the desired thickness within each array by altering the feed values whenever necessary. The classification described here is considerably more rapid and simple than classification based directly on flow measurements of the nozzles. Used nozzles can be returned and reclassified.

35

The invention is applicable e.g. to the classification of nozzles to be used for coating papers such as printing papers or cardboards. A classified nozzle array yields a coating of optimally even quality.

Description of the drawings

Some embodiments of the invention are described in detail below. The accompanying drawings pertain to the description.

Figure 1 shows the distribution of the yield and fan width of an unclassified nozzle array.

Figure 2 shows the change in the yield deviation of a nozzle array as the nozzles wear.

Figure 3 shows a typical deviation of the yield of a nozzle array and its classification in accordance with the invention.

Figure 4 shows optical measurement of the nozzle area.

Figure 5 shows the position of the two outermost nozzles in the nozzle array and the distribution of the coating achieved with these.

Detailed description of some embodiments of the invention

The manufacturing processes used by nozzle manufacturers are inaccurate. Manufacturers report a volume flow variation of the order of $\pm 5\%$ at the most for the nozzles. In the practice, this signifies that there may be a 10% variation in the coating amount profile. However, practical observations show that nozzles taken from a manufacturing batch of nozzles of the same nominal size may have a yield deviation of over $\pm 10\%$ from the determined mean yield.

The inventors examined the mass flow provided by each nozzle in a typical batch of 36 nozzles and the width of the jet fan using water under a pressure of 100 bars. The nominal diameter of the nozzles was 0.3 mm. The results are shown in table 1. The bars show the yield, and the curve shows the width of the jet fan.

It was also observed that, as the nozzles wear, the yield deviation tends to increase further. In fact, coating mixtures often contain solid substances, such as pigments, which accelerate wear. This issue was studied on a batch of nine nozzles by spraying a coating paste containing calcium carbonate and by monitoring the change in the volume flow deviation in the course of the operating time of the nozzles. The results are shown in table 2.

Consequently, it is of paramount importance that each nozzle in a nozzle array has the same initial yield with adequate accuracy. In this manner, a coating of optimally even quality is obtained.

5 For classifying the nozzles, a variable correlating with the yield is selected, which is determined for each nozzle. In terms of flow rate techniques, the nozzle opening area shows the most exact correlation with the flow. A satisfactory result is also obtained by measuring the diameter of the flow opening at one or more points. In the case of an oval opening, for instance, the width and the height can be determined. When these variables of the nozzle are substantially mutually equal, the mutual
10 yields will also be equal.

Only nozzles having a deviation of the determined variable lower than the allowable nominal deviation are mounted in the same nozzle array. The permissible limit may be e.g. $\pm 2\%$.
15

Figure 3 shows a typical deviation of the flow rate of a nozzle array, which has been divided into acceptable part arrays.

20 One way of classifying nozzles is to measure with a microscope the width and height of the nozzle opening and to use the product of these as a classification variable. A 100-fold magnifying microscope achieves 0.001 mm precision. The enclosed table shows the dimensions of the holes of a batch of 10 nozzles and the corresponding mass flow. The mass flow was obtained by spraying water under a pressure of 100 bars for 2 minutes into a vessel and by weighing the water amount.

25

Nozzle no	Width/mm	Length/mm	Length*width/mm ²	Mass flow/g/s
1	0.530	0.240	0.1272	12.6
2	0.525	0.235	0.1234	12.2
3	0.515	0.230	0.1185	11.8
4	0.515	0.230	0.1185	11.8
5	0.520	0.240	0.1248	12.4
6	0.515	0.235	0.1210	12.2
7	0.520	0.230	0.1196	12.0
8	0.500	0.225	0.1125	11.2
9	0.530	0.223	0.1182	11.6
10	0.515	0.230	0.1185	11.8

The width of an oval nozzle opening multiplied with its height is naturally greater than the opening area, but correlates perfectly well with the mass flow.

5

The nozzle opening area can be determined with high precision using e.g. the arrangement of figure 4. In this, a laser beam 3 having a diameter larger than the opening is taken from a laser source 1 to the opening of the nozzle 2. Having passed through the opening, the laser beam 4 is determined with a detector 5. The control and computing unit 6 calculates the difference between the laser beams, and using this as a basis, the opening area and also the main dimensions are calculated if desired. The results can be shown on a display. Such measuring apparatuses are commercially available (e.g. Keyence).

10

15 Optical measuring of the kind described above can also easily be automated.

Figure 5 shows the jet patterns 7.1 and 7.2 formed by fan-shaped jets of the two outermost nozzles 2.1 and 2.2 in a nozzle array and the weight distribution 8 of the formed coating. The jet edges are adequately overlapped in the intermediate area 9, so that the amount of coating becomes constant also in the area between the nozzles. When the nozzles have been classified in advance in accordance with the invention, the weight distribution will be optimally even across the entire web.

20

Claims

1. A nozzle array for use in the coating of a mobile web-like material, comprising a plurality of high-pressure nozzles (2.1, 2.2) in the transverse direction of the web,
5 the nozzles allowing a coating mixture to be sprayed onto the web, **characterised** in that the nozzles (2.1, 2.2) have been classified by a variable acting on the flow, so that the variable deviation within an array is smaller than a pre-set limit value.
2. A nozzle array as defined in claim 1, in which the acting variable is the area of
10 the nozzle opening or the diameter of the nozzle opening.
3. A nozzle array as defined in claim 2, in which the variable has been optically determined.
- 15 4. A nozzle array as defined in any of claims 1...3, in which the active variable has a deviation under 5% from the mean, such as less than 2% from the mean.
5. A method for classifying a high-pressure nozzle array (2.1, 2.2) used in the coating of a mobile web-like material, **characterised** in that a variable acting on the
20 flow is determined in the nozzles (2.1, 2.2), and the nozzles are classified by this variable so that the variable has a deviation within the array under a pre-set limit value.
- 25 6. A method for coating a mobile web-like material, **characterised** in that a nozzle array (2.1, 2.2) as defined in any of claims 1...4 or classified as in claim 5 is used in the coating.
